Create a getters and setters for each property and register them into the IViewModel instance. You can inject the required dependencies (GraphContext) and use the ViewModel to fill your RIA domain model from your View. Simple code could be something like:. This is a great technique for writing reusable ViewModels. To start, create a simple usercontrol that looks like this:. And register your for the viewmodel of this control:. When you inject this control into your view, it will automatically take care of registering the auto generated properties on the underlying ViewModel. To make the binding work, you will want to add an ID for the control like this:. Set the DataBinding property of your control to the ID you set in the data binding markup like this:. The control will now automatically bind to the ViewModel and each property of the ViewModel will be available to your usercontrol via simple object references. Try implementing a simple method like this:. Inject the required dependencies that your usercontrol needs into the constructor and call the method. Because this control does not have any View-specific logic, this control can easily be reused multiple times throughout your View. This is a great technique for writing reusable ViewModels. This is a great technique for writing reusable ViewModels. Now, you can write reusable ViewModels by defining an interface for the data that the View expects. This technique has been widely accepted by the RIA architecture and so is supported by Silverlight, ASP.NET MVC, Windows Store Apps, and Windows Phone. The idea behind using an interface for your ViewModels is to force all ViewModels to expose a common interface (via an interface) instead of specific data types. In this way, you can use a generic View to display any ViewModel. Now, if you create a ViewModel like this:. The ViewModel will automatically expose the types property that implements the interface you created. To tie this into your existing data, just create a different ViewModel like this:. The View will automatically bind to this ViewModel. When you define an interface in your ViewModel and in your view, you will force the ViewModel to expose a specific type and your View to bind to this specific type. If you want to force a View to bind to a specific object type, you can implement the interface in the View
